

PHP Code Refactoring Challenge

Task

Refactor the provided legacy PHP script into a modern, well-structured application while maintaining its original functionality. The script processes document records from a CSV file, filters them based on command-line parameters, and displays formatted results in a table.

Requirements

- Apply modern PHP 8.x features and best practices
- Transform the procedural code into a well-designed object-oriented solution
- Follow clean code principles to improve readability and maintainability
- Implement SOLID design principles
- Maintain the original functionality of the script

Example Usage

console: `php index.php invoice 1 12500`

OUTPUT:

document_id	document_type	partner name	total
1	invoice	Kovács József	25000
6	invoice	Kovács József	25000
10	invoice	Kovács József	42000

The refactored code must produce the same output as the original script when run with identical parameters.
